Instruction :
Design the API automation framework structure using REST Assured to test applications designed using microservices.
- Ask me 5 questions one by one for API automation framework structure creation
- Ask me the next question after answeing each question
-Step by Step implementation
Context :
As a automation architect have to build a robust API automation framework

REST ASSURED

API AUTOMATION FRAMEWORK

Microservices Testing Architecture Guide

Framework Technology Stack

Build Tool	Maven + Java 17
Test Framework	Cucumber + TestNG (BDD)
API Library	REST Assured
Reporting	TestNG HTML Report
Authentication	API Key / Header-based
Dependency Handling	WireMock + Pact + Live SIT
CI/CD Platform	GitLab CI
Config Management	Property Files (.properties)
Test Data	Excel/CSV (Apache POI)
Parallel Execution	Suite-level Parallelism

1. Framework Overview

This document defines the complete architecture, folder structure, design patterns, and implementation guidelines for a REST Assured-based API Automation Framework targeting a microservices ecosystem. The framework follows a BDD-driven, data-externalized, and CI/CD-integrated design built on Maven + Java 17, Cucumber + TestNG, and GitLab CI pipelines.

The framework is designed around five core principles:

- Modularity — Each microservice has its own isolated test module, enabling independent execution and maintenance.
- Reusability — Shared utilities, request builders, and response validators are centralized to eliminate duplication.
- Scalability — Suite-level parallel execution allows the framework to scale as the number of microservices grows.
- Observability — Structured logging, TestNG HTML reports, and GitLab pipeline artifacts provide end-to-end visibility.
- Shift-Left — WireMock stubs and Pact contract tests enable API testing without waiting for full environment availability.

2. Project Folder Structure

The framework uses a multi-module Maven project layout. Each microservice is an independent Maven module sharing a common parent POM, utilities, and configuration.

```

3. Maven Configuration

3.1 Parent POM (pom.xml)

The parent POM centralises all dependency versions, plugin configurations, and module declarations. Child modules inherit everything, keeping individual POMs minimal.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<project xmlns="http://maven.apache.org/POM/4.0.0">
  <modelVersion>4.0.0</modelVersion>
  <groupId>com.wealth.automation</groupId>
  <artifactId>api-automation-framework</artifactId>
  <version>1.0.0</version>
  <packaging>pom</packaging>

  <!-- Child Modules -->
  <modules>
    <module>common</module>
    <module>portfolio-service</module>
    <module>trading-service</module>
    <module>kyc-service</module>
    <module>risk-service</module>
  </modules>

  <properties>
    <java.version>17</java.version>
    <rest-assured.version>5.3.2</rest-assured.version>
    <cucumber.version>7.14.0</cucumber.version>
    <testng.version>7.8.0</testng.version>
    <poi.version>5.2.4</poi.version>
    <wiremock.version>3.3.1</wiremock.version>
    <pact.version>4.6.7</pact.version>
    <jackson.version>2.16.0</jackson.version>
    <lombok.version>1.18.30</lombok.version>
  </properties>

  <dependencyManagement>
    <dependencies>
      <!-- REST Assured -->
      <dependency>
        <groupId>io.rest-assured</groupId>
        <artifactId>rest-assured</artifactId>
```

```
        <version>${rest-assured.version}</version>
      </dependency>
      <!-- Cucumber BDD -->
      <dependency>

          <suiteXmlFiles>
            <suiteXmlFile>test-suites/testng-master-suite.xml</suiteXmlFile>
          </suiteXmlFiles>
        </configuration>
      </plugin>
      <plugin>
        <groupId>org.apache.maven.plugins</groupId>
```

```
        <artifactId>maven-compiler-plugin</artifactId>
        <version>3.11.0</version>
        <configuration>
          <source>17</source>
          <target>17</target>
        </configuration>
      </plugin>
    </plugins>
  </build>
</project>
```

4. Configuration Management

4.1 Environment Property Files

Each environment has a dedicated .properties file under the config/ directory. The active environment is selected at runtime by passing -Denv=sit to Maven, which the ConfigLoader reads to resolve the correct file.

```
# config/sit.properties

# Base URLs per microservice
portfolio.base.url=https://sit-api.wealth.com/portfolio
trading.base.url=https://sit-api.wealth.com/trading
kyc.base.url=https://sit-api.wealth.com/kyc
risk.base.url=https://sit-api.wealth.com/risk

# API Key Authentication
api.key.header=X-API-Key
api.key.value=${SIT_API_KEY}          # Injected from GitLab CI variable

# Timeouts (milliseconds)
connection.timeout=10000
read.timeout=30000

# WireMock
wiremock.host=localhost
wiremock.port=8089

# Parallel Execution
suite.thread.count=4
```

4.2 ConfigLoader.java

A thread-safe singleton that loads the correct properties file at startup and exposes typed getters used throughout the framework.

```
package com.wealth.common.config;

// Loads environment-specific .properties file at runtime
public class ConfigLoader {

  private static ConfigLoader instance;
  private final Properties props = new Properties();
```

```
  private ConfigLoader() {
    String env = System.getProperty("env", "sit");
    String path = "config/" + env + ".properties";
    try (InputStream is = new FileInputStream(path)) {
      props.load(is);
    } catch (IOException e) {
      throw new RuntimeException("Config not found: " + path, e);
    }
  }

  public static synchronized ConfigLoader getInstance() {
    if (instance == null) instance = new ConfigLoader();
    return instance;
  }

  public String get(String key) { return props.getProperty(key); }
  public int getInt(String key) { return Integer.parseInt(get(key)); }
}
```

5. Authentication Layer

5.1 ApiKeyAuthManager.java

Centralises API Key injection into every REST Assured RequestSpecification. The key and header name are sourced from the active environment's .properties file, and the value is supplied via GitLab CI masked variable to keep secrets out of source code.

```
package com.wealth.common.auth;

import io.restassured.specification.RequestSpecification;
import com.wealth.common.config.ConfigLoader;

public class ApiKeyAuthManager {

  private static final ConfigLoader config = ConfigLoader.getInstance();

  // Inject API Key header into any RequestSpecification
  public static RequestSpecification withApiKey(RequestSpecification spec) {
    return spec.header(
      config.get("api.key.header"),
      config.get("api.key.value"));
  }

  // For multi-key scenarios — pass key name explicitly
  public static RequestSpecification withApiKey(
      RequestSpecification spec, String headerName, String keyValue) {
    return spec.header(headerName, keyValue);
  }
}
```

6. REST Assured Base Client

6.1 RestAssuredClient.java

The base client builds a reusable, pre-configured RequestSpecification for each microservice. It sets the base URI, timeouts, content type, and injects the API key automatically. All service-specific API clients extend this class.

```
package com.wealth.common.client;

import static io.restassured.RestAssured.*;
import io.restassured.builder.RequestSpecBuilder;
import io.restassured.specification.RequestSpecification;
import com.wealth.common.auth.ApiKeyAuthManager;
import com.wealth.common.config.ConfigLoader;

public abstract class RestAssuredClient {

  protected RequestSpecification requestSpec;
  private static final ConfigLoader config = ConfigLoader.getInstance();

  protected RestAssuredClient(String baseUrlKey) {
    RequestSpecification spec = new RequestSpecBuilder()
      .setBaseUri(config.get(baseUrlKey))
      .setContentType("application/json")
      .setConfig(RestAssuredConfig.config()
        .httpClient(HttpClientConfig.httpClientConfig()
          .setParam("http.connection.timeout", config.getInt("connection.timeout"))
          .setParam("http.socket.timeout",     config.getInt("read.timeout"))))
      .addFilter(new RequestLoggingFilter())
      .addFilter(new ResponseLoggingFilter())
      .build();

    this.requestSpec = ApiKeyAuthManager.withApiKey(spec);
  }

  // Child classes call these fluent methods
  protected Response get(String path) {
    return given().spec(requestSpec).when().get(path);
  }
  protected Response post(String path, Object body) {
    return given().spec(requestSpec).body(body).when().post(path);
  }
  protected Response put(String path, Object body) {
    return given().spec(requestSpec).body(body).when().put(path);
  }
  protected Response delete(String path) {
    return given().spec(requestSpec).when().delete(path);
  }
}
```

7. Service-Specific API Clients

7.1 PortfolioApiClient.java

Each microservice has a dedicated API client that extends RestAssuredClient. It encapsulates all endpoint paths for that service, making step definitions clean and business-readable.

```
package com.wealth.portfolio.api;

import com.wealth.common.client.RestAssuredClient;
import io.restassured.response.Response;
```

```java
public class PortfolioApiClient extends RestAssuredClient {

  private static final String BASE_URL_KEY = "portfolio.base.url";
  private static final String PORTFOLIOS    = "/v1/portfolios";
  private static final String PORTFOLIO_BY_ID = "/v1/portfolios/{id}";
  private static final String VALUATION    = "/v1/portfolios/{id}/valuation";

  public PortfolioApiClient() { super(BASE_URL_KEY); }

  public Response getAllPortfolios() {
    return get(PORTFOLIOS);
  }

  public Response getPortfolioById(String portfolioId) {
    return given().spec(requestSpec)
      .pathParam("id", portfolioId)
      .when().get(PORTFOLIO_BY_ID);
  }

  public Response createPortfolio(PortfolioRequest request) {
    return post(PORTFOLIOS, request);
  }

  public Response getValuation(String portfolioId) {
    return given().spec(requestSpec)
      .pathParam("id", portfolioId)
      .when().get(VALUATION);
  }
}
```

8. BDD Layer — Feature Files & Step Definitions

8.1 Portfolio Feature File

```
# features/portfolio.feature

Feature: Portfolio Management API
  As a Wealth Manager
  I want to manage client portfolios via the API
  So that I can automate portfolio operations end-to-end

  Background:
    Given the Portfolio API is available

  @smoke @portfolio
  Scenario Outline: Get portfolio by ID returns correct data
    When I request portfolio with ID "<portfolioId>"
    Then the response status code should be <statusCode>
    And the portfolio name should be "<portfolioName>"
    And the portfolio currency should be "<currency>"

    Examples:
      | portfolioId | statusCode | portfolioName       | currency |
      | PF-001      | 200        | Growth Portfolio    | USD      |
      | PF-002      | 200        | Income Portfolio    | GBP      |
      | PF-999      | 404        | N/A                 | N/A      |
```

```
  @regression @portfolio
  Scenario: Create a new portfolio successfully
    Given I have portfolio creation data from "portfolio testdata.xlsx" sheet
"CreatePortfolio"
    When I submit the create portfolio request
    Then the response status code should be 201
    And the response should contain a valid portfolio ID
```

8.2 PortfolioSteps.java

```
package com.wealth.portfolio.steps;

import io.cucumber.java.en.*;
import io.restassured.response.Response;
import static org.hamcrest.Matchers.*;

public class PortfolioSteps {

  private final PortfolioApiClient client = new PortfolioApiClient();
  private Response response;
  private PortfolioRequest request;

  @Given("the Portfolio API is available")
  public void verifyApiAvailability() {
    client.getAllPortfolios().then().statusCode(anyOf(is(200), is(401)));
  }

  @When("I request portfolio with ID {string}")
  public void requestPortfolioById(String portfolioId) {
    response = client.getPortfolioById(portfolioId);
  }

  @Then("the response status code should be {int}")
  public void verifyStatusCode(int expectedCode) {
    response.then().statusCode(expectedCode);
  }

  @Then("the portfolio name should be {string}")
  public void verifyPortfolioName(String expectedName) {
    if (!expectedName.equals("N/A")) {
      response.then().body("name", equalTo(expectedName));
    }
  }

  @Given("I have portfolio creation data from {string} sheet {string}")
  public void loadTestData(String file, String sheet) {
    Map<String,String> data = ExcelDataReader.readRow(file, sheet, 0);
    request = PortfolioRequest.builder()
      .name(data.get("portfolioName"))
      .currency(data.get("currency"))
      .clientId(data.get("clientId"))
      .build();
  }

  @When("I submit the create portfolio request")
  public void submitCreateRequest() {
    response = client.createPortfolio(request);
  }
}
```

9. Test Data Management

9.1 ExcelDataReader.java — Apache POI

The ExcelDataReader reads test data from .xlsx files using Apache POI. It returns rows as Maps of column-header → cell-value, making data consumption in step definitions intuitive and type-safe.

```
package com.wealth.common.data;

import org.apache.poi.xssf.usermodel.*;
import java.util.*;

public class ExcelDataReader {

  // Read a single row by index (0-based), returns header→value map
  public static Map<String,String> readRow(String filePath, String sheetName, int rowIndex) {
    Map<String,String> dataMap = new LinkedHashMap<>();
    try (FileInputStream fis = new FileInputStream(resolveDataPath(filePath));
         XSSFWorkbook workbook = new XSSFWorkbook(fis)) {
      XSSFSheet sheet = workbook.getSheet(sheetName);
      XSSFRow headers = sheet.getRow(0);
      XSSFRow dataRow = sheet.getRow(rowIndex + 1);
      for (int i = 0; i < headers.getLastCellNum(); i++) {
        String header = headers.getCell(i).getStringCellValue();
        String value  = getCellValue(dataRow.getCell(i));
        dataMap.put(header, value);
      }
    } catch (IOException e) {
      throw new RuntimeException("Failed to read Excel: " + filePath, e);
    }
    return dataMap;
  }

  // Read ALL data rows — useful for data-driven loops
  public static List<Map<String,String>> readAllRows(String filePath, String sheet) {
    List<Map<String,String>> rows = new ArrayList<>();
    // ... iterate from row 1 to lastRowNum, same pattern as above
    return rows;
  }

  private static String getCellValue(XSSFCell cell) {
    return switch (cell.getCellType()) {
      case STRING  -> cell.getStringCellValue();
      case NUMERIC -> String.valueOf((long) cell.getNumericCellValue());
      case BOOLEAN -> String.valueOf(cell.getBooleanCellValue());
      default      -> "";
    };
  }

  private static String resolveDataPath(String fileName) {
    return System.getProperty("user.dir") + "/src/test/resources/testdata/" + fileName;
  }
}
```

10. WireMock — Service Mocking

10.1 WireMock Stub Configuration

WireMock stubs simulate downstream microservices, enabling isolated testing when dependent services are unavailable. Stubs are defined as JSON mapping files and loaded automatically at test startup via Hooks.java.

```
// wiremock/stubs/portfolio_stubs.json
{
  "request": {
    "method": "GET",
    "urlPattern": "/v1/portfolios/PF-001"
  },
  "response": {
    "status": 200,
    "headers": { "Content-Type": "application/json" },
    "jsonBody": {
      "portfolioId": "PF-001",
      "name": "Growth Portfolio",
      "currency": "USD",
      "totalValue": 2500000.00
    }
  }
}
```

10.2 Hooks.java — WireMock Lifecycle

```
package com.wealth.portfolio.hooks;

import com.github.tomakehurst.wiremock.WireMockServer;
import static com.github.tomakehurst.wiremock.core.WireMockConfiguration.options;
import io.cucumber.java.*;

public class Hooks {

  private static WireMockServer wireMock;
  private final ConfigLoader config = ConfigLoader.getInstance();

  @BeforeAll
  public static void startWireMock() {
    int port = config.getInt("wiremock.port");
    wireMock = new WireMockServer(options()
      .port(port)
      .usingFilesUnderDirectory("src/test/resources/wiremock"));
    wireMock.start();
  }

  @AfterAll
  public static void stopWireMock() {
    if (wireMock != null) wireMock.stop();
  }

  @Before
  public void resetWireMock() {
    wireMock.resetAll();
  }
}
```

11. Parallel Execution — TestNG Suite

11.1 testng-master-suite.xml

Suite-level parallelism runs each microservice test suite in its own thread. This maximises execution speed while keeping test data, WireMock instances, and state completely isolated per suite.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE suite SYSTEM "http://testng.org/testng-1.0.dtd">

<!-- parallel="suites" runs each <suite-file> in its own thread -->
<suite name="Wealth Banking API Suite" parallel="suites" thread-count="4" verbose="1">

  <suite-files>
    <suite-file path="../portfolio-service/src/test/resources/testng-portfolio.xml"/>
    <suite-file path="../trading-service/src/test/resources/testng-trading.xml"/>
    <suite-file path="../kyc-service/src/test/resources/testng-kyc.xml"/>
    <suite-file path="../risk-service/src/test/resources/testng-risk.xml"/>
  </suite-files>

</suite>
```

11.2 Service-Level TestNG (testng-portfolio.xml)

```
<suite name="Portfolio Service Suite" verbose="1">
  <test name="Portfolio API Tests">
    <classes>
      <class name="com.wealth.portfolio.runner.PortfolioTestRunner"/>
    </classes>
  </test>
</suite>
```

11.3 Cucumber TestRunner

```
package com.wealth.portfolio.runner;

import io.cucumber.testng.AbstractTestNGCucumberTests;
import io.cucumber.testng.CucumberOptions;

@CucumberOptions(
  features = "src/test/resources/features",
  glue    = {"com.wealth.portfolio.steps", "com.wealth.portfolio.hooks"},
  plugin  = {"pretty", "html:target/reports/portfolio-report.html",
             "json:target/reports/portfolio-report.json"},
  tags    = "@portfolio and not @wip"
)
public class PortfolioTestRunner extends AbstractTestNGCucumberTests {}
```

12. GitLab CI Pipeline

12.1 .gitlab-ci.yml

The GitLab CI pipeline defines three stages: build, test, and report. API key values are stored as GitLab CI masked variables and injected at runtime — never hardcoded in the repository.

```yaml
# .gitlab-ci.yml

stages:
  - build
  - test
  - report

variables:
  MAVEN_OPTS: "-Xmx2g -Dmaven.repo.local=$CI_PROJECT_DIR/.m2"
  ENV: "sit"  # Override per pipeline trigger

cache:
  paths:
    - .m2/

# ── Stage 1: Compile & validate ──────────────────────
build:
  stage: build
  image: maven:3.9-eclipse-temurin-17
  script:
    - mvn clean compile -q
  only:
    - merge_requests
    - main

# ── Stage 2: Execute API tests (parallel suites) ────────
api-tests:
  stage: test
  image: maven:3.9-eclipse-temurin-17
  variables:
    SIT_API_KEY: $SIT_API_KEY   # GitLab CI masked variable
  script:
    - mvn test -Denv=$ENV -DSIT_API_KEY=$SIT_API_KEY
  artifacts:
    when: always
    paths:
      - "**/target/reports/**"
      - "**/target/surefire-reports/**"
    expire_in: 7 days
  only:
    - merge_requests
    - main

# ── Stage 3: Publish TestNG HTML report ────────────────
publish-report:
  stage: report
  script:
    - echo "Reports published as GitLab artifacts"
  dependencies:
    - api-tests
  artifacts:
    reports:
      junit: "**/target/surefire-reports/*.xml"
  only:
    - main
```

13. Pact Contract Testing

Pact consumer-driven contract tests define the expected API contract between the test (consumer) and each microservice (provider). Pact files are published to a Pact Broker and verified by the provider CI pipeline, catching breaking changes before integration.

```
package com.wealth.portfolio.contract;

import au.com.dius.pact.consumer.dsl.*;
import au.com.dius.pact.consumer.junit5.*;

@ExtendWith(PactConsumerTestExt.class)
@PactTestFor(providerName = "portfolio-service", port = "8090")
public class PortfolioContractTest {

  @Pact(consumer = "wealth-api-tests")
  public RequestResponsePact getPortfolioPact(PactDslWithProvider builder) {
    return builder
      .given("portfolio PF-001 exists")
      .uponReceiving("a request for portfolio PF-001")
        .path("/v1/portfolios/PF-001")
        .method("GET")
        .headers("X-API-Key", "test-key")
      .willRespondWith()
        .status(200)
        .body(new PactDslJsonBody()
          .stringType("portfolioId")
          .stringType("name")
          .stringType("currency"))
      .toPact();
  }

  @Test @PactTestFor(pactMethod = "getPortfolioPact")
  void verifyGetPortfolio(MockServer mockServer) {
    Response response = new PortfolioApiClient(mockServer.getUrl())
      .getPortfolioById("PF-001");
    response.then().statusCode(200)
      .body("portfolioId", notNullValue());
  }
}
```

14. Design Patterns & Best Practices

Pattern	Applied In	Benefit
Builder Pattern	PortfolioRequest, all POJO models	Fluent, readable object construction in step definitions
Singleton Pattern	ConfigLoader, ApiKeyAuthManager	Single config load per suite; no duplicate property reads
Chain of Responsibility	RestAssured filter chain	Pluggable logging, auth injection, retry logic per request
Page Object (API Object)	Service API Clients	Encapsulates all endpoints; step definitions stay business-level
Strategy Pattern	Auth Manager variants	Swap auth strategy per service without changing clients

Factory Pattern	TestData factory methods	Centralise POJO construction from Excel rows

15. Framework Capability Summary

Capability	Status	Details
Multi-environment support	✅Implemented	DEV / SIT / UAT via -Denv Maven property
API Key Authentication	✅Implemented	Header injected via ApiKeyAuthManager from CI variable
BDD Scenario Coverage	✅Implemented	Cucumber feature files per microservice, tag-based filtering
Excel Data-Driven Testing	✅Implemented	Apache POI ExcelDataReader, row & sheet selection
Service Mocking	✅Implemented	WireMock stubs loaded from JSON per service module
Contract Testing	✅Implemented	Pact consumer-driven contracts published to Pact Broker
Suite Parallel Execution	✅Implemented	4 suites run in parallel via TestNG thread-count
CI/CD Integration	✅Implemented	GitLab CI pipeline with artifact publishing
Secrets Management	✅Implemented	GitLab CI masked variables for API keys
Test Reporting	✅Implemented	TestNG HTML + JSON reports per service module
